PROJECT INFORMATION

Natural and man-made disasters such as floods, earthquakes, cyclones, and landslides often cause large-scale damage to life and property. In such situations, it becomes essential to efficiently manage the collection and distribution of resources, coordinate relief centers, track donations, and organize volunteers to ensure timely support to affected regions. Managing all this information manually is complex, time-consuming, and prone to errors. The Disaster Relief Management System aims to simplify and streamline disaster management operations through a structured database-driven approach. It helps in storing, organizing, and retrieving vital data related to disaster events, relief centers, donors, volunteers, and resources. The system allows quick access to updated information and ensures that aid reaches the right place at the right time. This project focuses on developing a relational database model that can efficiently handle multiple aspects of disaster relief operations. It integrates various modules such as event management, donor management, resource allocation, and request tracking to support effective decision-making during emergencies. By implementing this system, authorities and organizations can improve coordination, enhance transparency, and ensure a faster and more organized relief process.
